Orthogonal Trajectories

Out[22]= - Graphics -

Finding the constant c in terms of a particular point (x0,y0), and substitute back to the equation:

tuto-06.nb

3

$$In[8] := \begin{array}{l} \text{eqn1} = \mathbf{y} == \mathbf{c} \, \mathbf{E}^{\wedge} (\mathbf{x}^{\wedge} \mathbf{2}) \\ \text{particularpoint} = \text{Solve}[\text{eqn1}, \mathbf{c}] /. \{\mathbf{x} \rightarrow \mathbf{x}0, \mathbf{y} \rightarrow \mathbf{y}0\} \end{array}$$

$$Out[8] = \mathbf{y} == \mathbf{c} \, \mathbf{e}^{\mathbf{x}^{2}}$$

$$Out[9] = \left\{ \left\{ \mathbf{c} \rightarrow \mathbf{e}^{-\mathbf{x}0^{2}} \, \mathbf{y}0 \right\} \right\}$$

$$In[10] := \begin{array}{l} \text{eqn2} = \text{First}[\text{eqn1} /. \text{particularpoint}] \end{array}$$

$$Out[10] = \mathbf{y} == \mathbf{e}^{\mathbf{x}^{2} - \mathbf{x}0^{2}} \, \mathbf{y}0$$

Then, differentiate the whole equation and define m1=y'[x0], which is the slope at (x0,y0). Afterwards, replace (x0,y0) with (x,y) to get the general solution of the derivative.

In[11]:= del = D[eqn2 /. y
$$\rightarrow$$
 y[x], x] /. x \rightarrow x0
m1 = Last[del] /. {x0 \rightarrow x, y0 \rightarrow y}
Out[11]= y'[x0] == 2 x0 y0
Out[12]= 2 x y

For the orthogonal trajectories, we find their slope m2 at point (x,y) by using the slope of the previous equation, m1

$$In[13] := \mathbf{m2} = -1/\mathbf{m1}/.\mathbf{y} \rightarrow \mathbf{y}[\mathbf{x}]$$

$$Out[13] = -\frac{1}{2 \times \mathbf{y}[\mathbf{x}]}$$

Because m2 is the slope, we define y'[x]=m2 and solve for y[x].

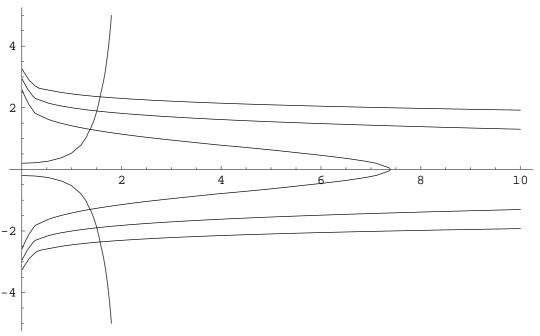

$$In[14] := trajsol = DSolve[y'[x] == m2, y[x], x]$$

$$Out[14] = \{ \{y[x] \rightarrow -\sqrt{2C[1] - Log[x]} \}, \{y[x] \rightarrow \sqrt{2C[1] - Log[x]} \} \}$$

$$In[15] := trajs = y^2 == Last[Last[trajsol]]]^2$$

$$Out[15] = y^2 == 2C[1] - Log[x]$$

Now we get the equation in implicit form. So we plot it using ImplicitPlot.

Out[32]= - Graphics -
